

# Job Description: Solutions Engineer

**Location:** Bengaluru, KA | **Type:** Full-time | **Experience:** Fresher — Class of 2026 (or recent graduate) | **Travel:** Client sites, as needed

## About Vinterra

At Vinterra, we build real-time, edge-deployed AI systems that transform passive video feeds into actionable intelligence. Our platform runs high-performance deep learning models directly on edge hardware (such as NVIDIA Jetson Orin) to deliver low-latency video analytics, anomaly detection, and vector-based search at scale.

## About the Role

This role is for someone joining us straight out of college, and it is where our product meets the real world. Alongside a senior engineer you will understand what a client needs, configure our platform to fit their environment, set it up on their edge devices and cloud tenant, integrate it with the VMS and access control systems they already run, and prove it works on their cameras. Cameras are badly placed, networks drop, and a model that scored well on a benchmark still has to hold up on a real site — that is the work. The bugs you file and the enhancements you scope go straight to our engineering leads.

## What You Will Work On

- **Requirements Discovery:** Sit in on client conversations — security, operations, IT — and help turn what they need into a solution design
- **Solution Configuration & Enhancement:** Configure and adapt our platform to each client's requirements — tuning pipelines, adjusting model behaviour, and writing the code that closes the gap between product and deployment
- **Deployment & Cloud Enablement:** Install and commission our software on edge devices (NVIDIA Jetson class) at client sites, and set up their cloud tenant — camera onboarding, device provisioning, users, sites, and alerts
- **Systems Integration:** Code and configure integrations with the client's existing VMS and access control (ACS) systems — REST APIs, webhooks, and event bridges
- **Validation & Field Feedback:** Test each deployment for stability and accuracy against real site footage, tune thresholds and placement, and feed bugs and enhancements back to engineering

## What We're Looking For

### Must-haves

- **Degree Background:** B.E. / B.Tech, M.Tech, BCA / MCA, or B.Sc. / M.Sc. in Computer Science, Electronics, Electrical Engineering, or a related technical field
- **Engineering Foundations:** A working grasp of data structures, networking basics (TCP/IP, ports, firewalls, VPNs), and Linux on the command line
- **Coding Ability:** Comfortable writing Python (and reading C/C++) to configure pipelines, build integrations, and automate deployment and test steps

- **APIs & Systems Glue:** You can read API documentation and wire two systems together — and debug it when the payload is not what the docs promised
- **A Testing Instinct:** You test what you deploy, write down what you measured, and can tell a model problem from a configuration problem or a camera problem
- **Clear Communication:** You can hold a requirements conversation with a non-technical stakeholder, write a clear bug report, and ask questions early
- **Ownership in the Field:** Deployments rarely go to plan — stay calm on site and escalate with a proposal, not just a symptom. Comfortable travelling to client sites

### **Nice-to-haves**

Hands-on experience is not required — curiosity and foundational knowledge are what count, whether picked up through a course, an internship, or a personal project.

- **Video & Surveillance Stack:** Exposure to VMS platforms (Milestone, Genetec, or similar), ONVIF / RTSP camera streams, or access control systems
- **Computer Vision Basics:** Familiarity with OpenCV, object detection architectures (e.g., YOLO variants), or how detection accuracy is measured
- **Edge & Cloud Tooling:** Curiosity about NVIDIA Jetson, TensorRT or ONNX Runtime, or exposure to Docker and cloud consoles (AWS / Azure / GCP)

## **What You Will Learn in Your First Year**

- How a real-time video AI system is actually delivered — from requirements conversation through commissioning, validation, and handover.
- Edge deployment in practice: Jetson hardware, device provisioning, camera onboarding, and how enterprise security stacks — VMS, ACS, networks, cloud tenants — fit together.
- How to evaluate model effectiveness in the field, and how to debug a live system.

## **Where You Could Be in Two Years**

- Owning customer deployments end-to-end, from first requirements call to signed-off, stable production system. Develop a industry specific domain knowledge on what matters to customers. Grow into an Account Manager for important customers.
- The person engineering trusts on what the field needs — shaping the roadmap through the enhancements you scope, and leading solution design for new use cases
- A track record of live deployments across real customer sites that would take four or five years to accumulate at a larger company, plus mentoring the next Solutions Engineer.

## **Why Join Us?**

- **Mentorship & Code Reviews:** Work directly with experienced founders and engineers who review your code, pair with you when you're stuck, and are genuinely invested in how fast you level up
- **A Collegial, Low-Ego Team:** A flat, first-name culture where the best argument wins regardless of who makes it, asking questions is never a bad look, and no one is too senior to help you debug
- **Team Hangouts:** Frequent team lunches, and celebratory outings whenever we ship something big
